

# Why Disorder is Interesting

All argon atoms are the  
same....

...but every colloidal  
particle is different.

This has interesting consequences  
for their physical behavior.

# POLYDISPERSITY IN HARD-SPHERE COLLOIDS

Polydispersity postpones, and eventually suppresses, hard-sphere freezing)

$$\text{Polydispersity: } s \equiv (\langle r^2 \rangle - \langle r \rangle^2)^{1/2} / \langle r \rangle$$

# Phase diagram of polydisperse hard spheres

(Bolhuis & Kofke, PRE, 54:634(1996))

# POLYDISPERSITY IN LYOTROPIC LIQUID CRYSTALS

Lyotropic liquid crystals:

Liquid crystals consisting of mesoscopic (10nm-1 $\mu$ m) building blocks.

(Examples: colloids, virus particles, rigid polymers).

Hard-core liquid lyotropic crystals  $\Rightarrow$   
Ordering is entropy-driven

Crystal

Smectic

Entropy driven formation of liquid crystals of rod-like colloids

 = Direction of increasing density

But there is one other possibility to consider:

Rodlike particles could form a **COLUMNAR** phase.

Can hard, rodlike particles form a columnar phase?

Simulations (JCP, 106:666(1997)) show:

No columnar phase for “short” rods ( $L/D < 60$ )

*Maybe for very long rods??*

*(  $L/D \Rightarrow \infty$  )*

Problem...

Limit  $L/D \Rightarrow \infty$ :

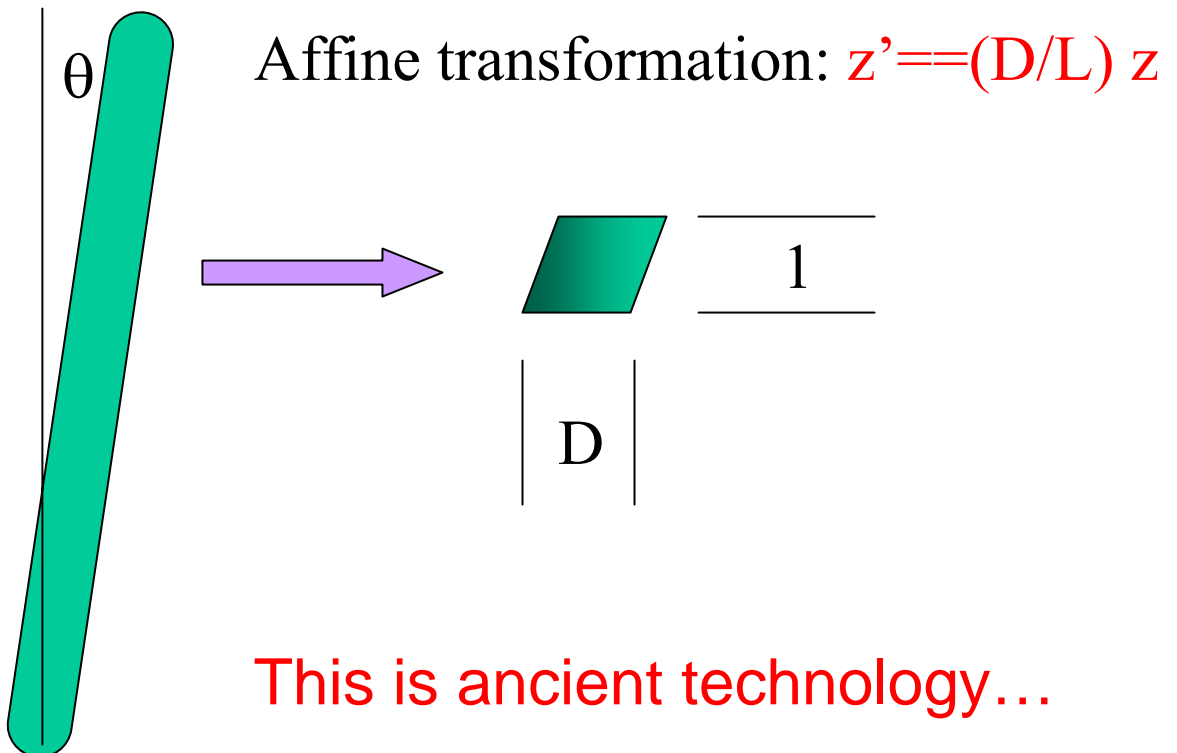

Simulations impossible???

Box volume  $\sim L^3$

$N \sim L^3/(LD^2) = O(L^2/D^2) \Rightarrow \infty$

\* \* \* \* \*

At high densities, the nematic phase is strongly aligned.  $\{\theta = O(D/L) \Rightarrow 0\}$

... No columnar phase.

Clearly, we need something else.

## Polydispersity

WHY?

Monodisperse  
smectic

Polydisperse  
smectic

Monodisperse  
columnar

Polydisperse  
columnar

Polydispersity can be a good thing:

It can *induce* phases that are not stable in mono-disperse systems.

# CRYSTAL NUCLEATION in COLLOIDS

1. The effect of polydispersity
2. The effect of the interaction range

# Homogeneous nucleation...

## ...the basics

**Nucleation requires supercooling**

(e.g. :  $\mu_{\text{solid}} < \mu_{\text{liquid}}$  )

**Physicist's Crystal nucleus**

Free - energy gain

$$\Delta G_{Bulk} = \frac{4\pi}{3} \rho r^3 \Delta\mu_{s,l} < 0$$

Free - energy loss :

$$\Delta G_{Surface} = 4\pi r^2 \gamma_{s,l} > 0$$

$r^3$

$r^2$

How good is this  
description?

# Classical Nucleation Theory

(CNT)

**assumes that:**

**Crystal nuclei have the  
same properties**

**(structure, density,  
surface free energy)**

**as bulk crystals.**

...is that true?

# Test by “Computer Experiment”

HOWEVER:  
NUCLEATION IS A  
RARE EVENT

Hence:

1. EXPERIMENTS ARE DIFFICULT, and
2. BRUTE-FORCE SIMULATIONS WON'T WORK...

# What is the problem?

Experimental nucleation rates:

$$O(1) \text{ cm}^{-3} \text{ s}^{-1}$$

Simulation:

Volume is much smaller (e.g. for one million particles):  $V = O(10^{-15}) \text{ cm}^3$

$\Rightarrow$  Nucleation rate  $O(10^{-15}) \text{ s}^{-1} !!$

$\Rightarrow$  One event per  $10^{15} \text{ s}$

$\Rightarrow$  One event per  $10^{30} \text{ MD time steps}$

$= 10^{15} \text{ years with}$

**“Blue Gene”**

## Solution:

1. Compute height of the free-energy barrier  $\Delta G^*$  (MC/MD)
2. Compute transmission coefficient  $\Gamma$  (MD)

Rate =  $\Gamma$

$$\exp(-\beta\Delta G^*)$$

Probability of “critical” fluctuation

(strong function of T)

Kinetic Prefactor

(usually weak function of T)

*Determine Free-energy Barrier,  
using:*

*Biased sampling  
("umbrella sampling")*

**Simulation allows us to study:**

- 1. The **structure** of the critical nucleus.**
- 2. The **height** of the nucleation barrier**
- 3. The nucleation **rate****

# Testing Classical Nucleation Theory

## CRYSTAL NUCLEATION of

## COLLOIDAL HARD SPHERES

(entropic freezing transition)

## WHY THIS SYSTEM?

1. **THEORY/SIMULATION:** We know “everything” about the equilibrium properties of hard spheres.
2. **EXPERIMENT:** Suspensions of uncharged *silica* or *PMMA* colloids **really behave like hard-sphere systems**
3. **..AND:** There is experimental information on hard-sphere nucleation. (Ackerson & Schaezel, Harland & van Megen: on earth. Cheng, Zhu, Chaikin et al.: in  $\mu$ -gravity)

**However:**

**Entropy-driven freezing is not  
universally loved...**

SIMULATION RESULTS  
for BARRIER HEIGHT

Nothing special???

As  $\Delta\mu$  is known, we can deduce  $\gamma$  from the barrier heights.

**SIMULATIONS:**

**Supersaturated:**  $\gamma_{\text{eff}} \approx 0.72 \text{ kT}/\sigma^2$

**At coexistence:**  $\gamma \approx 0.62 \text{ kT}/\sigma^2$

In contrast, **CNT ASSUMES THAT  $\gamma$  IS CONSTANT.**

**20% error does not seem much, but:**

$$\Delta G^* \sim \gamma^3$$

**And the nucleation rate is proportional to**

$$\exp[-16\pi\gamma^3/(3\rho^2\Delta\mu^2kT)]$$

# Absolute nucleation **rates** ?

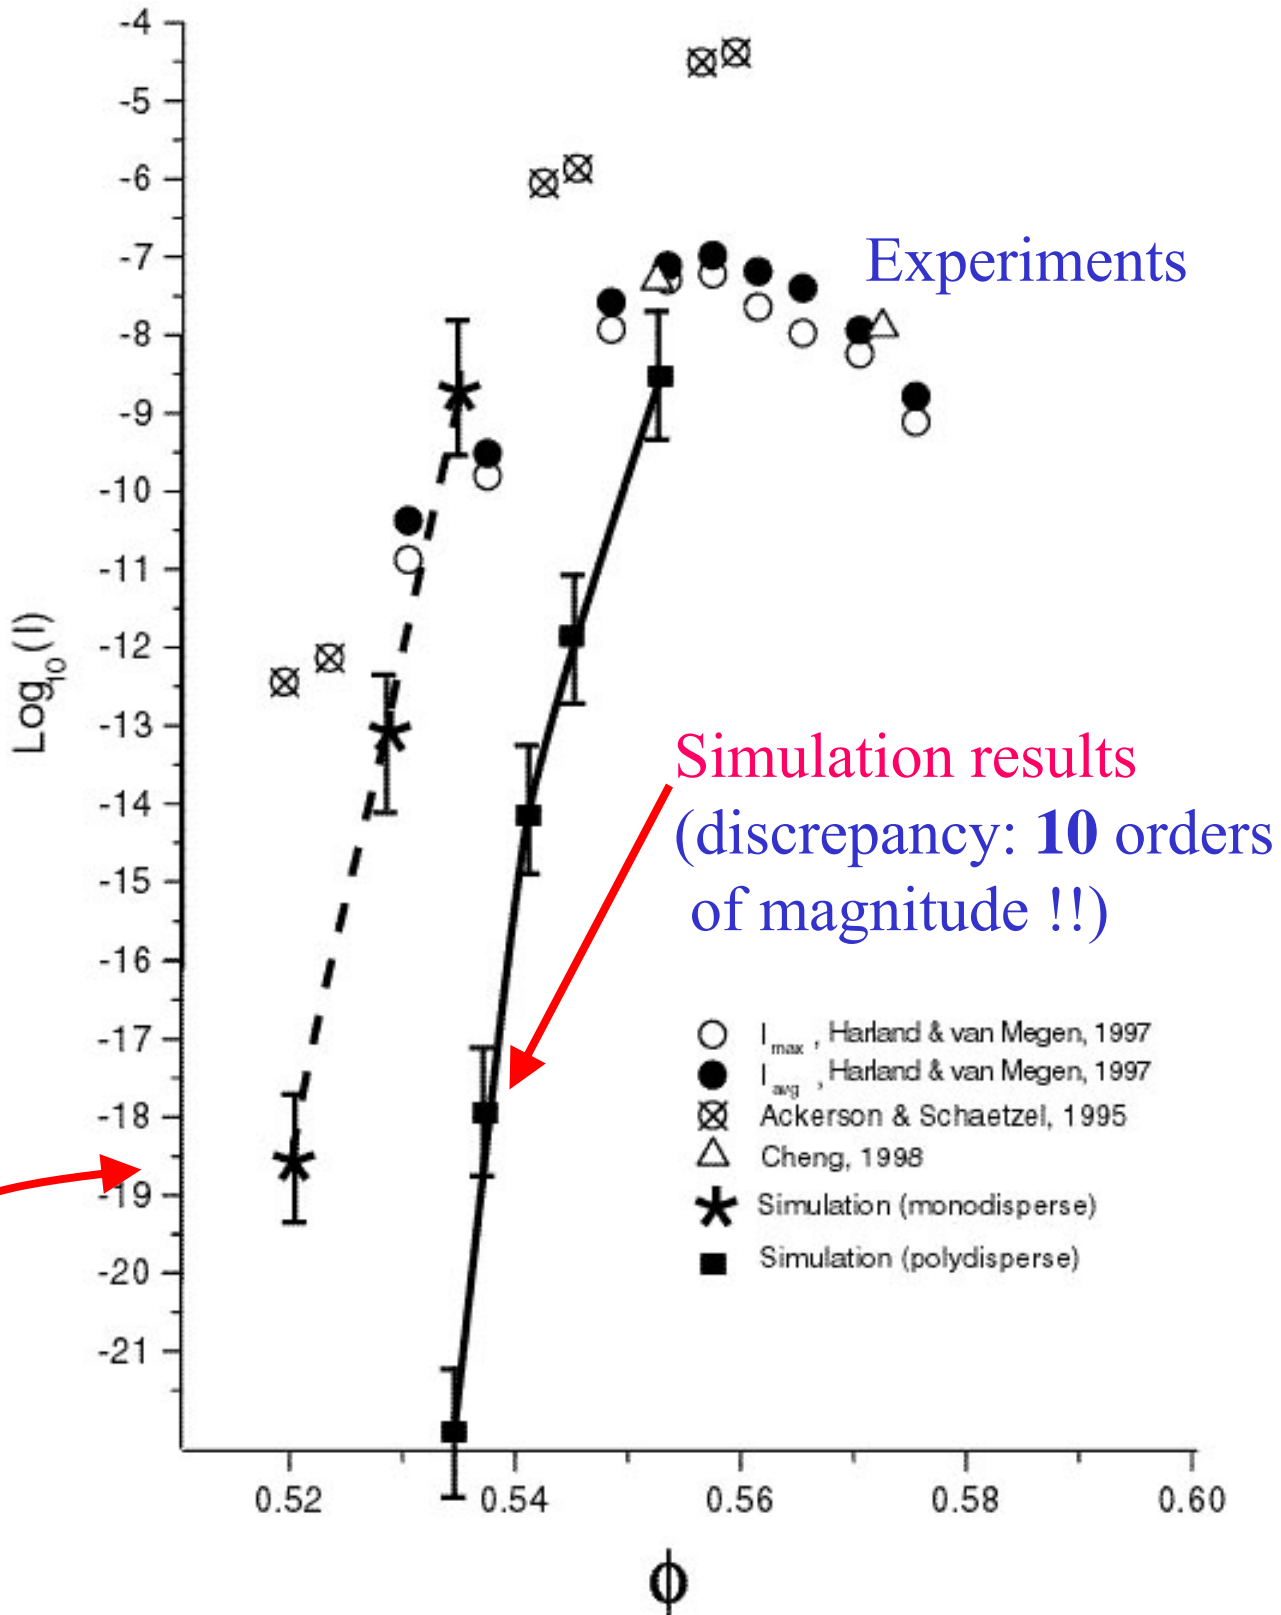

Assume : Brownian motion  
Approximate : Hydrodynamic  
Interactions

Nucleation rate: **Zeldovich Factor**

$$I = k_{N^*}^+ Z \rho \exp(-\Delta G^*/kT)$$

**$k_{N^*}^+$  ,  $Z$ ,  $\Delta G^*$  can all be  
computed numerically**

# COMPARISON WITH EXPERIMENT

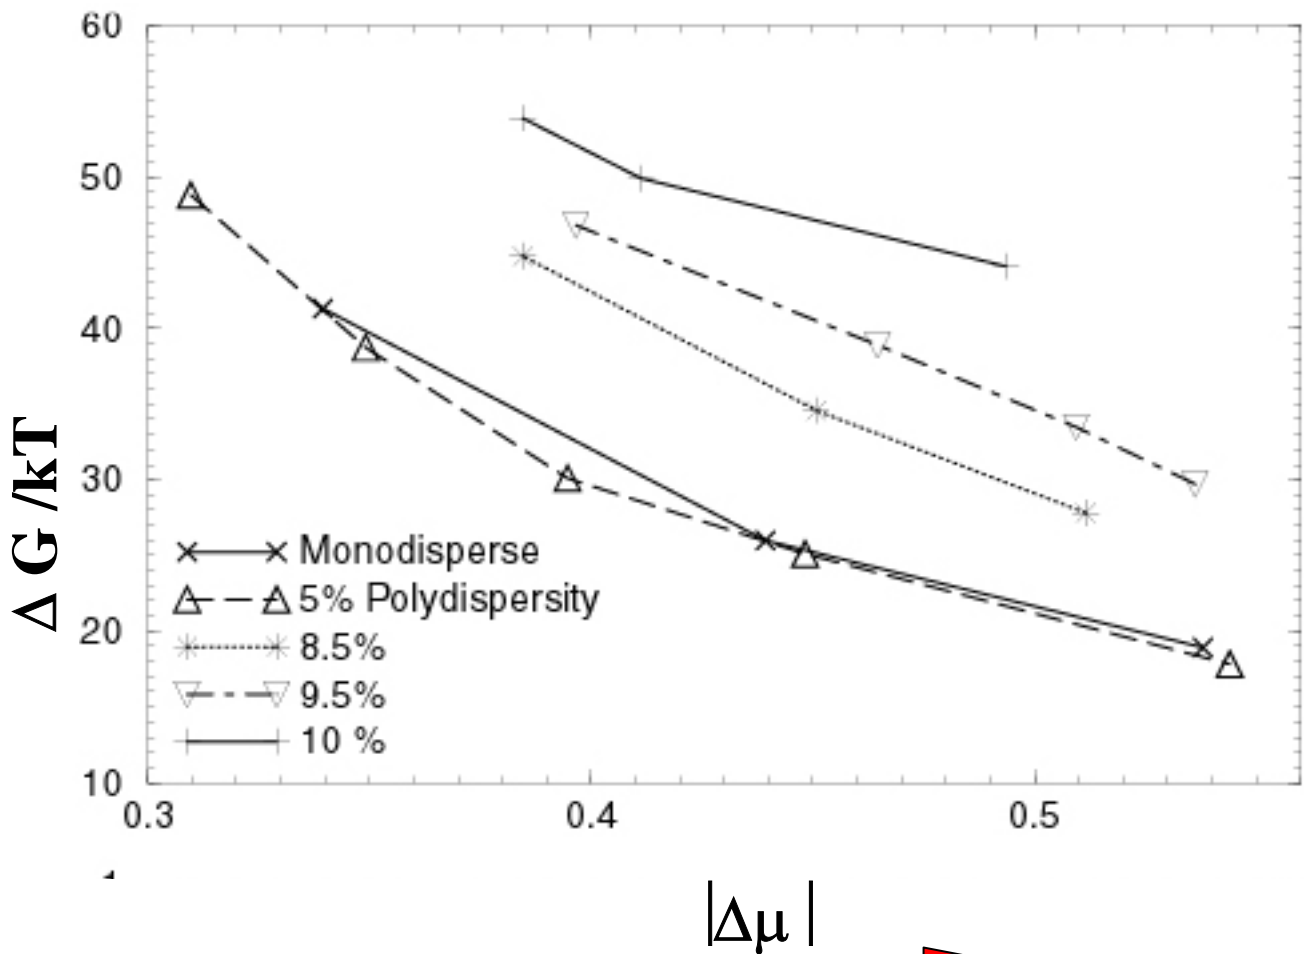

≈ 1 Nucleus / (month cm<sup>3</sup>)

# **THE EFFECT OF POLYDISPERSITY**

# Phase diagram of polydisperse hard spheres

**(Bolhuis & Kofke, PRE, 54:634(1996))**

**Increasing supersaturation**

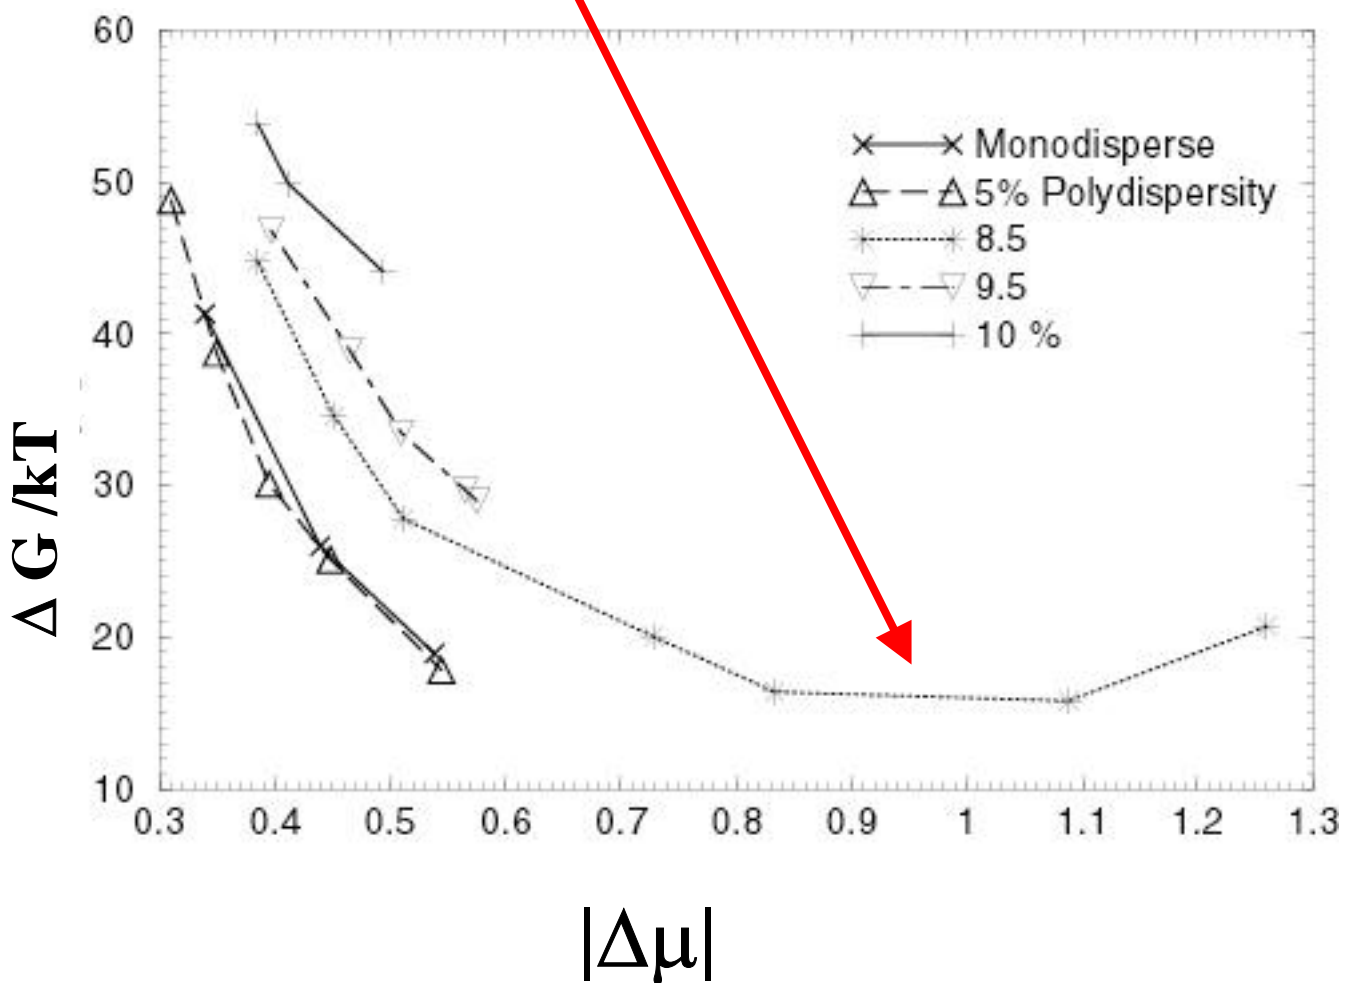

- × monodisperse
- Δ 5% polydispersity
- \* 8.5 %
- ∇ 9.5 %
- + 10 %

For low polydispersity (up to 5%), the nucleation barrier is the same as for monodisperse spheres.

But for larger polydispersity, the barrier becomes **much** larger...

Moreover...

# It goes through a minimum!!!

**Increasing supersaturation**

That is not predicted by  
standard CNT...

**Implications for glass  
formation**

## Experiments:

Hard sphere liquids with polydispersity larger than 12 % do not crystallize  
(Pusey, 1987)

Why not?

“Conventional” answer:

**The polydisperse fluid  
vitrifies before it  
freezes.**

This slows down both  
**nucleation and growth.**

But the nucleation barrier itself  
will be low.

If this were true, glasses should  
contain very many, very small  
crystallites that simply cannot  
grow.

We find:

In polydisperse colloids,  
the nucleation barrier is  
**large.**

Colloidal glasses are  
therefore NOT nano-  
crystalline but truly  
amorphous.

**Any experimental evidence???**

Maybe...

Logarithm of average crystallite  
SIZE should be proportional to

$$\Delta G^* / k_B T$$

**F. Shi et al. Appl.Phys.Lett. 67, 350(1995)**

A minimum in the nucleation barrier then implies:

1. For small supersaturation:  
**LARGE CRYSTALS**
2. For higher supersaturation:  
**SMALL CRYSTALS**
3. For still higher supersaturation:  
**LARGE CRYSTALS**

*Evidence?*

# Effect of short-ranged attractions on crystallization

Recall: Short-ranged attractive forces change the appearance of the phase diagram of colloidal suspensions:

Hard spheres with  
with  
**LONG-  
RANGED**  
attraction

Hard spheres with  
with  
**SHORT-  
RANGED**  
attraction

**Meta-stable  
fluid-fluid**

# GLOBULAR PROTEINS

*Problem:*

HUMAN GENOME PROJECT

$3 \cdot 10^4$  proteins

BUT WHAT IS THEIR 3D STRUCTURE?

**X-RAY CRYSTALLOGRAPHY**  
**REQUIRES GOOD CRYSTALS**

**CRYSTALLIZED PROTEINS:**

$O(8 \cdot 10^3)$  - globular proteins

$O(20)$  - membrane proteins

M. Broide *et al.* , PNAS **88**,5660(1991)

# Phase diagram of **GLOBULAR PROTEINS**

( $\gamma$ -crystallin)

D. Rosenbaum, P.C. Zamora and C.F. Zukoski.  
**PRL, 76150(1996)**

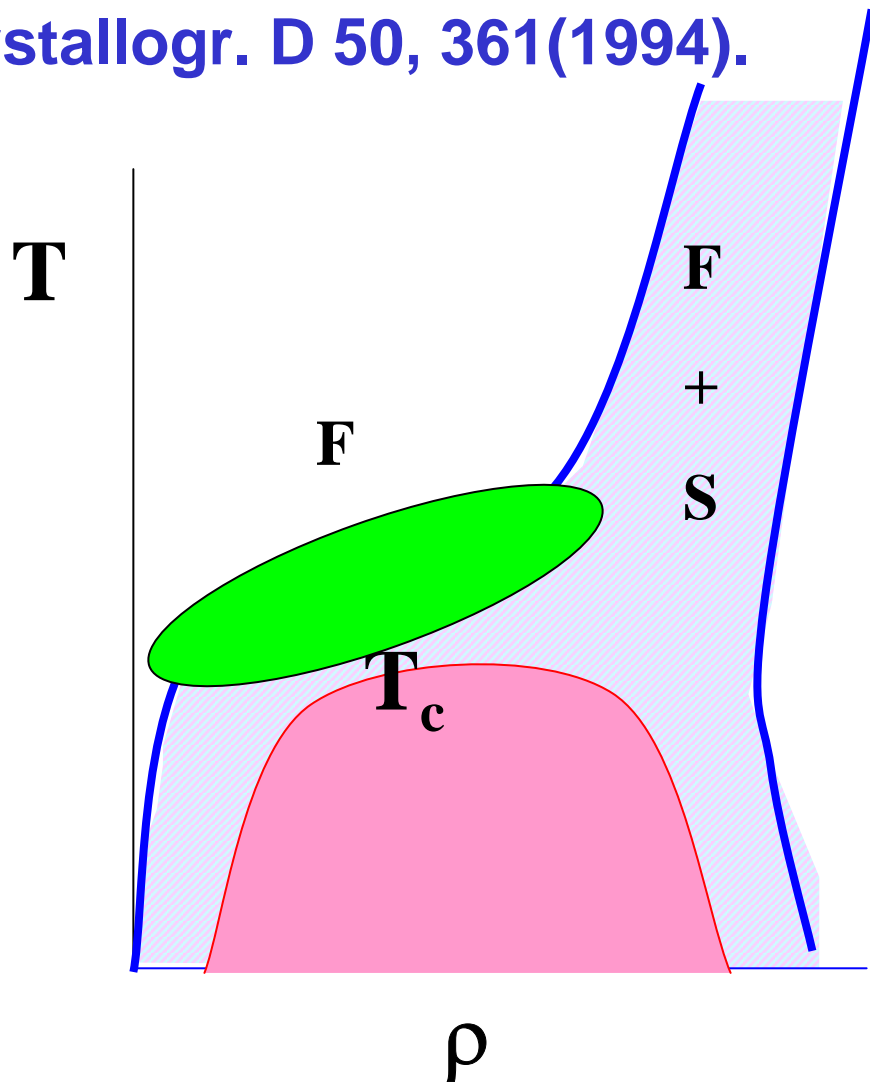

**RELATION BETWEEN PHASE  
DIAGRAM AND  
PROTEIN-CRYSTALLIZATION  
“WINDOW”**

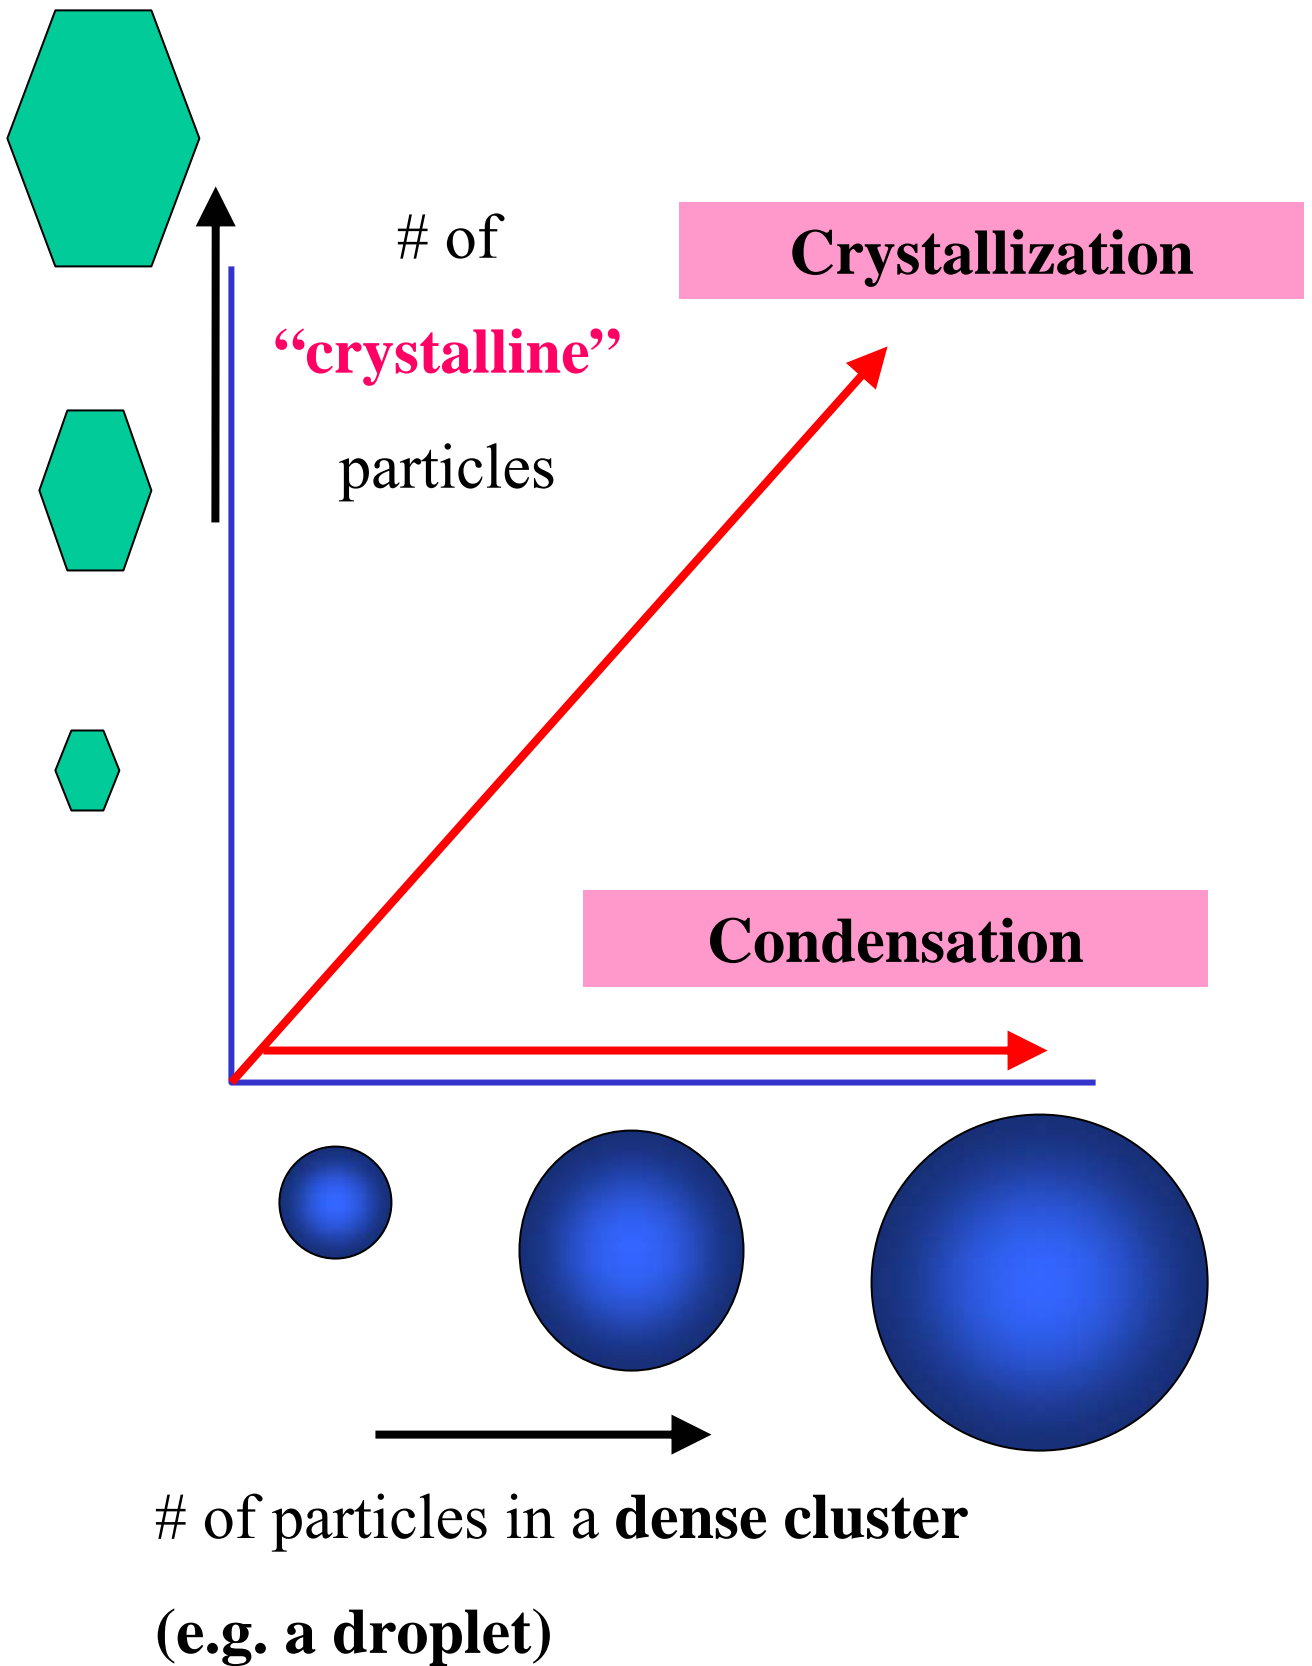

# WHY DO GLOBULAR PROTEINS CRYSTALLIZE IN A NARROW “WINDOW” ??

A. George and W. Wilson,

Acta.Crystallogr. D 50, 361(1994).

USE **SIMULATION** TO STUDY THE  
NUCLEATION PATHWAY...

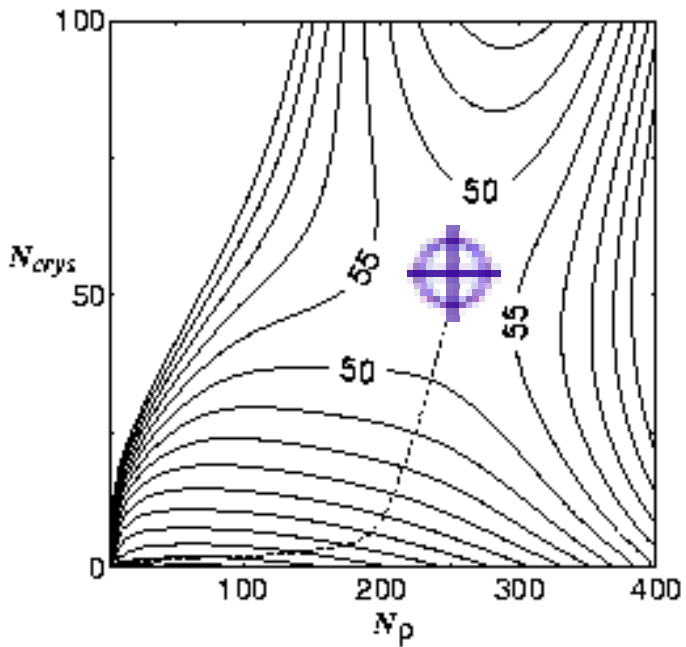

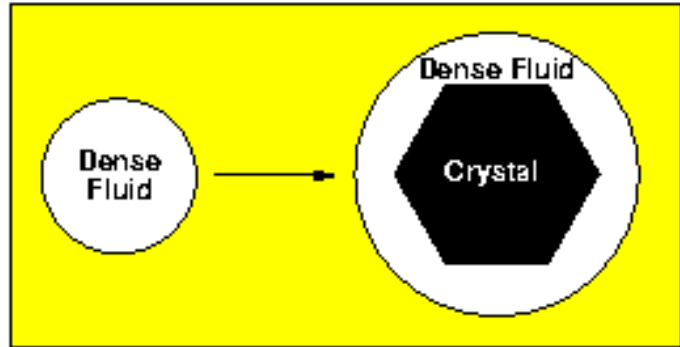

**P.R. ten Wolde & D.F.**

**SCIENCE, 277,1975(1997)**

**A**

**B**

At fixed supersaturation, this corresponds to an increase in the nucleation rate by a factor:

$10^{13}$  !

*A hidden critical point helps!*

# SUMMARY

- 1. Nucleation can be studied by simulation**
- 2. The structure of the critical nucleus is (often) not as predicted, and...**
- 3. The barrier height is not as predicted, and ...**
- 4. The rate is not as predicted...**

**In short: we need better experiments and better theories....**
